## 2011 VERMONT SMALL GRAIN FORAGE TRIALS

## **INTRODUCTION**

In 2011, the University of Vermont Extension continued their research evaluating several organic annual forage models. Spring cereal grains such as oats, barley, triticale, wheat, and spelt could have the potential to provide high yield and quality feed for livestock. Spring grains are planted in mid to late April and can be harvested at various stages of development. The objective of this project was to evaluate yield and quality of spring grains harvested in the vegetative, milk, or soft dough stage. The overall goal of this project is to help organic dairy producers reduce their reliance on expensive concentrates through the production of a variety of high quality annul forages. In addition, we were interested in investigating the value of combining brassica forage with these cool season annuals.

### **METHODS**

In 2011, an organic small grain forage trial was conducted at Borderview Research Farm in Alburgh, VT (Table 1). The farm is certified organic by Vermont Organic Farmers, LLC. The previous crop was organic corn silage. The seedbed was prepared by conventional tillage methods. Plots were planted with a six-inch grain drill on May 13, 2011. The oats, barley, spelt, and triticale were planted at 125 lbs/acre. The Barkant turnips were planted at 8 lbs/acre. The varieties and seed source are in Table 2. All plots measured 5' x 20' and were fertilized with Pro-Booster organic fertilizer at a rate of 70 lbs. N acre<sup>-1</sup> on June 28, 2011. Each treatment was harvested at three development stages, vegetative stage, milk stage, and soft dough stage. Subsamples of approximately 2.5 ft<sup>2</sup> were cut to the ground, dried at 40°C, and weighed to determine dry matter yield. Oven dry samples were coarsely ground with a Wiley mill (Thomas Scientific, Swedesboro, NJ) and sent to Cumberland Valley Analytical Services, Inc. (Hagerstown, MD) for quality analysis. Results were analyzed with an analysis of variance with SAS (Cary, NC).

# **RESULTS AND DISCUSSION**

Seasonal precipitation and temperature recorded at a weather station in close proximity to Alburgh, VT is reported in Table 3. This season started off with above average rain in April and May. This delayed cereal grain planting into mid-May. Ideally planting would have been completed by April. Precipitation was below average during each harvest date.

levels and the highest total digestible nutrients (TDN), net energy of lactation (NEL), and non-structural carbohydrates (NSC). Fiber digestibility (dNDF) was greatest for the oat treatments. The addition of turnip into the seeding did not appear to impact quality. Overall, yields were similar or lower when turnips were added to the mix. A higher proportion of turnips may have resulted in higher CP and less fiber concentration but would also further decrease dry matter yields. Future work on seed mixes would help us better understand if this combination of forages is viable for the dairy community.

### Milk Stage Harvest

Oats alone had the greatest dry matter yields when harvested in the milk stage, 5620 lbs dry matter acre<sup>-1</sup> (Table 7 and Figure 3). Wheat, triticale and oats had the highest milk stage protein levels, from 11.1 - 11.7%. The barley treatments had the lowest milk stage ADF and NDF levels (Figure 4), while oat, barley, and spelt had the highest digestible NDF levels. The barley treatments also had the highest total digestible nutrients, net energy of lactation and non-structural carbohydrates. Addition of turnips into the grain mix did not seem to impact forage quality.
